Research on the Exploration of Methods to Produce Chlorates and Perchlorates by Means other Than Electrolytic

I. OBJECTIVE

The objectives of this study of the lead dioxide process for producing perchlorates were the following:

- To review and check the results claimed by Ott (1) and Erhardt (2) for the process:
 PbO₂ + KClO₃ + H₂SO₄ → PbSO₄ + KClO₄ + H₂O
- 2 To reduce the time of the above oxidation step by adjusting concentrations and temperature.
- 3. To develop an economical method for the regeneration of lead dioxide.
- 4. To test the feasibility of cyclic operation.
- 5. To evaluate the chemical specifications of the product.
- 6. To evaluate the lead dioxide process, as developed, from the cost view point.

II. SUMMARY

Each of the objectives of this study has been achieved as of below:

- 1. The process of Ott (1) and Erhardt (2) to produce potassium perchlorate, KClO₄, by direct oxidation of potassium chlorate, KClO₃, with lead dioxide, PbO₂, was found valid.
- 2. The duration of the exidation stage has been reduced by our modifications from 4 hours to 2 hours.
- 3. A very satisfactory method for regenerating PbO₂ from lead sulphate, PbSO₄ has been developed. Low cost sodium carbonate, Na₂CO₃ and dilute chemical chlorine are the reagents.
- 4. Cyclic operation of the entire process is satisfactory.
- 5. The product meets the major specification for KClO₄ One recrystallation will be necessary to reduce KClO₃ content to specification; lead and sulfate ion content are well within limits.

III. INTRODUCTION

The laboratory-scale production of potassium perchlorate by oxidation of KClO₃ with PbO₂ was studied by Ott (1) and Erhardt (2) in 1943. The oxidation occurred as follows:

KClO₃ + H₂SO₄ + PbO₂ \longrightarrow KClO₄ + PbSO₄ + H₂O

To achieve a 91.6% conversion of KClO₃ to KClO₄ Ehardt combined the following reagents with constant mixing for 4 hours at 84°C.

1.0 moles KClO₃
16.7 moles H₂O
3.37 moles H₂SO₄
1.63 moles PbO₂
0.103 moles PbO

produced 0.916 moles of KClO₄

The KClO₄ was extracted from the solid products with hot water; the residual PbSO₄ was regenerated to PbO₂ and recycled. For the latter regeneration step Erhardt suggested three methods, none of which he considered fully satisfactory. The aim of the present research has been (1) to reduce the time of the oxidation reaction and (2) to develop a satisfactory method for regenerating PbO₂. It will be seen that both of these ends have now been achieved.

IV. EXPERIMENTAL PREPARATION OF PERCHLORATE FROM CHLORATE WITH PbO2

A. OXIDATION

KClO₃ can be oxidized to KClO₄ in an acid medium by the oxidizing agent PbO₂.

a.
$$KClO_3 + H_2SO_4 + PbO_2 \rightarrow KClO_4 + H_2O + PbSO_4$$

During the formation of potassium perchlorate there are also two competing reactions.

b.
$$H_2SO_4 + 3KCIO_3 \rightarrow 2CIO_2 + K_2SO_4 + KCIO_4 + H_2O$$

c.
$$H_2SO_4 + PbO_2 \Rightarrow H_2O + PbSO_4 + 1/2O_2$$

Since the rates of reaction (a), (b) and (c) are dependent principally on (1) concentration and (2) temperature, these variables were studied and the results are listed in Table II shows corresponding studies for the preparation of NaClO₄ from NaClO₃.

166	1.0	16	3.4	8.3	65 105	40	7	93

1. Concentration

The concentration of $\rm H_2SO_4$ affects the rate of all three reactions. When 50–65 weight percent acid is used the reaction (a) proceeds smoothly. However, reaction (b) gives rise to explosion as the concentration approaches 70 weight percent. This is due to the acceleration of reaction (b) evolving more $\rm ClO_2$. Increased concentration of $\rm H_2SO_4$ also increases the reaction (c) between $\rm H_2SO_4$ and $\rm PbO_2$. Hence at a high concentration of acid above approximately 70 weight percent, the oxidizing agent $\rm PbO_2$ is destroyed. However, an advantage of a

high concentration of acid is the production of greater yields of potassium perchlorate by reaction (a) when the acid concentration is increased from 50 to 70 weight percent. The hazard of explosion of ClO₂ exists. Therefore, the displacement of ClO₂ with N₂, CO₂. O₂ or O₃ is necessary to prevent explosion.

The optimum concentration range of H_2SO_4 is 55-65 weight percent where reaction (a) is accelerated but the side reactions (b) and (c) are less pronounced.

2. Temperature

Temperature also affects the rate of reactions (a), (b) and (c). The formation of ClO₂, reaction (b), is increased slightly but not seriously with an increase in temperature. This effect is shown by plotting the percent conversion of KClO₃ to KClO₄ at various temperatures (Figure I.).

At higher temperatures the efficiency of PbO_2 in reaction (a) is increased (Figure I), the optimum range being $100-115^{\circ}$ C. Temperature accelerates reaction (a) greatly resulting in an increase of $KClO_4$ yield. At 115° C 80% yield of $KClO_4$ is obtained but only 15% at 65° C (Figure I).

These results show that the optimum temperature is between $100-115^{\circ}$ C where the maximum efficiency of PbO₂ is obtained plus a high yield of KClO₄.

B. REGENERATION

To regenerate the spent residue, PbSO₄, Erhardt (2) gives three methods. They are as follows:

- Treatment with bleach (Hypochlorite)
 Pb^cJ₄ + 2NaOH + NaOC1 → PbO₂ + Na₂SO₄ + H₂O + NaC1
- 2. Fusion with sodium nitrate
 PbSO₄ + 2NaOH + 2NaNO₃ → PbO₂ + 2Na₂SO₄ + NO + NO₂ + H₂O
- 3. Stepwise treatment $PbSO_4 + 2NH_3 + CO_2 + H_2O \rightarrow PbCO_3 + (NH_4)_2SO_4$ $PbCO_3 + 2Ca(OH)_2$ at $800^{\circ}C \rightarrow Ca_2PbO_4 + H_2O + CO_2$ $Ca_2PbO_4 + 4HNO_3 \rightarrow PbO_2 + 2Ca(NO_3)_2 + 2H_2O$

Although Erhardt found (3) most suitable due to continuing market for the by-products and because electricity need not be spent, we have rejected it due to high handling and treating costs. Schlachter (1) also anticipated equipment difficulties for method (3).

We have therefore explored other methods for regenerating the spent residue, PbSO4.

The following were considered:

- (4) Fusion of NaClO3 and PbSO4,
- (5) Chlorination of PbCO3 produced from PbSO4, and
- (6) Ozonolysis of PbCO₃.

- 4 A series of experiments was performed to determine if NaClO₃ would easily regenerate PbO₂ from PbSO₄. It was found that fusion of NaClO₃ and PbSO₄ did produce PbO₂, but not very effectively, needing a large excess of NaClO₃ and a high temperature (600°C). This method was abandoned since further studies produced a simpler method to convert the spent residue to PbO₂.
- 5. The new method is to convert the PbSO₄ to PbCO₃, by either Na₂CO₃ or NaHCO₃ and then chlorinating the PbCO₃ to produce PbO₂. F. Aurebach (3) converted PbSO₄ to PbCO₃ by either Na₂CO₃ or NaHCO₃. It is necessary to have high speed stirring in order to convert the sulfate effectively.

Equations:

Step 1:

PbSO₄ + Na₂CO₃
$$\xrightarrow{\text{PbCO}_3}$$
 PbCO₃ + Na₂SO₄

PbSO₄ + 2NaHCO₃ $\xrightarrow{\text{PbCO}_3}$ PbCO₃ + Na₂SO₄ + H₂O + CO₂

Step 2:

$$H_2O$$
 $Cl_2 + Na_2CO_3 + PbCO_3 \longrightarrow PbO_2 + 2NaCl + 2CO_2$

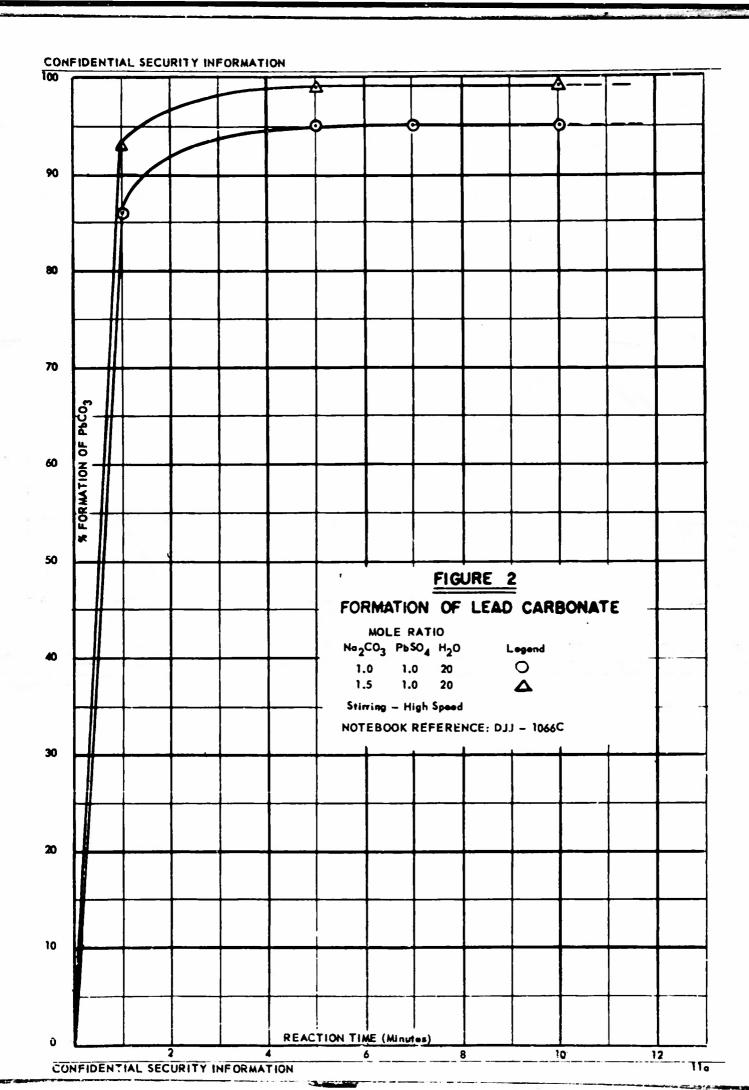

Table III shows that both Na₂CO₃ and NaHCO₃ give excellent conversions.

TABLE III

		(NaHCO 3)						
80-2	1.0	2.0	222	60	29	0	100	

^{*}Conversion is based on PbSO₄ remaining in product and is uncertain to the extent that the average molecular weight of product varied as hydrolysis of PbCO₃ to Pb(OH)₂ occurred. Figure 2 shows that increasing the concentration of Na₂CO₃ increases the rate of formation of PbCO₃.

Temperature has no pronounced effect on the conversion of PbSO₄ to PbCO₃ but it does tend to increase the formation of the basic carbonate due to hydrolysis of PbCO₃. F. LeFort (4) found that if the lead salt is hot, an alkali carbonate will precipitate basic lead carbonate 2PbCO₃ · Pb(OH)₂; normal lead carbonate is formed only in cold solutions. The equation for the hydrolysis is:

$$3PbCO_3 + H_2O → 2PbCO_3 \cdot Pb(OH)_2 + CO_2$$

This hydrolysis does not decrease the ultimate yield of PbO₂ since 2PbCO₃ · Pb(OH)₂ is equally well converted to PbO₂ by chlorine. In the chlorination step 2, PbO₂ is probably formed when NaOCl reacts with PbCO₃, NaOCl being produced when gaseous chlorine reacts with Na₂CO₃.

Equations:

$$Na_2CO_3 + Cl_2 \rightarrow NaOCl + NaCl + CO_2$$

 $NaOCl + PbCO_3 \rightarrow NaCl + CO_2 + PbO_2$

Other substitutes for Na₂CO₃ are either NaOH or NaHCO₃ since both yield NaOCl when they react with chlorine. Table IV shows the excellent conversions of PbCO₃ to PbO₂ with 80% efficiency based on chlorine.

CONVERSION OF PbCO₃ TO PbO₂

Exp.	N	doles of Res	gents		Ph range	Temp	Time	% PbO2
No.	рьсо3	Na2CO3	Cl ₂	H ₂ O		°C	Min	Formed
134-1	1.0	1.0	_	195	10.2-6.9	80°	38	77.6
13d-3	1.0	1.2 (NoHCO ₃)	1.19	195	10.1-7.0	80°	35	98.7
15a-1	1.0	2.4 (NoOH)	1.1	195	8.3-6.0	80°	45	97.3
13b	1.0	2.0	-	195	12,2-3,4	80°	50	94.6

It is necessary to control the pH to the extent that it does not fall below 7, otherwise $Pb^{\frac{1}{2}}$ ions will be lost in the filtrate.

Equations:

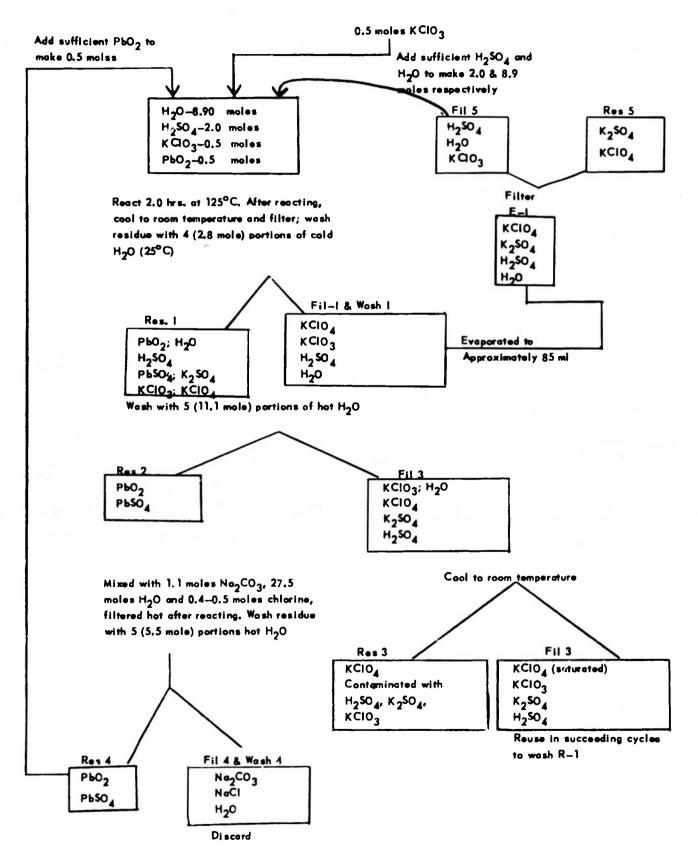

$$H_2O + Cl_2 \rightarrow HCl + HOCl$$
 $PbO_2 + 2HCl \rightarrow PbCl_2 + H_2O + 1/2 O_2$

6. Qualitative determination showed that ozone is capable of converting PbCO₃ to PbO₂ in dry, aqueous, or acid state but the high cost of ozone makes it uneconomical at present. Sidgwick (5) also states that ozone is capable of oxidizing Pb(OH)₂ to PbO₂.

C. CYCLIC OPERATION

To determine whether both oxidation and regeneration can function together in a cycle without seriously affecting each other, a bench scale pilot plant was operated. The schematic diagram, Figure 3 gives in detail the manner in which the cycle was performed.

FIGURE III POTASSIUM PERCHLORATE CYCLE

The experimental procedure was as follows employing stock grade chemicals.

A solution consisting of 2.0 moles $\rm H_2SO_4$ and 8.9 moles $\rm H_2O$ was placed in a one liter reaction flask equipped with a condenser, thermometer and a mechanical stirrer. The flask was heated by means of an oil bath at 100° C. Then 0.5 moles $\rm KClO_3$ and 0.5 moles $\rm PbO_2$ were thoroughly mixed and added slowly to the stirred $\rm H_2SO_4$ — $\rm H_2O$ solution. Since the reaction is exothermic its temperature rose to approximately 125° C; additional external heat was supplied from the oil bath to bring it up to 125° C and maintain it there during the reaction time. After the 2 hour reaction time had elapsed the reaction flask was removed from the oil bath and allowed to cool to room temperature where it was filtered through a medium porous glass filter. The spent residue (R-1) on the filter was washed four times with 2.8 mole portions of cold water (25°C) to remove most of the adhering $\rm H_2SO_4$ from the residue. The filtrate (F-I) and washings (W-I) were combined and evaporated to a volume of approximately 85–100 ml. to prepare them for recycling. The residue (R-I) on the filter was then washed five times with 11.1 mole portions of hot water (90°-100°C) to remove all the KClO₄ from the residue (R-I). The solution (F-3) was cooled to room temperature (25-30°C) where crystallization occured. The KClO₄ crystals (R-3) were separated from the mother liquor by filtration.

The spent residue (approximately 0.5 moles PbSO₄) was removed from the filter and mixed with 1.1 moles Na₂CO₃ and 27.5 moles H₂O in a one liter reaction flask equipped with a high speed stirrer, thermometer and a porous glass gas diffuser. This mixture was also heated by an oil bath at 80–90°C for 0.5 hours stirring violently throughout the reaction time. Then this mixture was chlorinated with 0.4–0.5 moles of chlorine at the rate of lg. Cl₂/minute. After sufficient chlorine had been added the mixture was filtered hot on a medium porous glass filter and the residue was washed five times with 5.5 mole portions of hot H₂O (95–100°C) to remove Na₂CO₃, Na₂SO₄ and NaCl from the PbO₂ – PbSO₄ residue (R-4) which was recycled repeatedly.

To prepare the materials which are recycled in the reactious, first the evaporated solution (E-I) was filtered to remove any small amounts of KClO₄ and K₂SO₄ crystals which had formed. Then the solution (F-5) which contained about 1-1.4 moles H₂SO₄ and 0.4-0.6 moles H₂O was increased to its original concentration by the addition of H₂SO₄ and H₂O remembering not to include the H₂O present in the wet PbO₂ residue (R-4). Also due to the inability to remove all of the PbO₂ (R-4) from the filter addition of enough PbO₂ to make 0.5 moles was necessary. To test the various compositions small samples were removed during the cycle.

The reactions in the second cycle were carried out in the same manner as in the first utilizing the recycled materials. On this and succeeding cycles the mother liquor (F-3), saturated with $KClO_4$ at room temperature, was used to wash residue (R-2). This technique enables more $KClO_4$ to crystallize out of the mother liquor. The hot mother liquor $(90^{\circ}-100^{\circ}C)$ was divided into 4 equal parts to wash the residue (R-2) containing PbO_2 , $PbSO_4$ and $KClO_4$. It was also necessary to wash residue (R-2) with 2 additional 2.8 mole portions of hot water after washing with the mother liquor to remove the $KClO_4$ completely. These operations were continued until 5 cycles were completed.

Table 5 gives the results of various operations in the cycle.

TABLE V

Percentage Yield					
Based on PbSO ₄	92%	87%	89%	87%	81%
Based on Cl ₂	107%	87%	103%	87%	110%

In the oxidation step of cycle 5 the KClO₄ yields have approached static conditions, 74% based on KClO₃ and 80% based on PbO₂; hence additional cycles would give corresponding results. To obtain the greatest efficiency from the KClO₃, conditions should be such that all KClO₃ reacts in the oxidation step since any unreacted KClO₃ is immediately destroyed when evaporating the H₂SO₄ solution, the reactivity being due to the concentrating of scid. As a result, the by-products ClO₂ and K₂SO₄ are formed and the latter contaminates the end product. This situation can be easily remedied by concentrating the filtrate and washing (F-1 and W-1) with sulfur trioxide thereby greatly decreasing the reaction between H₂SO₄ and KClO₃ which is accelerated at temperatures above 70°C.

The regeneration of PbSO₄ to PbO₂ gave an 87% average yield based on PbSO₄ and a 99% average chlorine efficiency. Note that this efficiency is much superior to those reported for batch runs in Table IV. Careful metering of chlorine is of necessity not only to avoid waste of chlorine but also to maintain the pH above 7 to prevent formation of PbCl₂. The only loss of lead encountered was of mechanical nature, none resulting through chemical reactions.

The product KClO₄ obtained in the cycles was more than 99% pure, the maximum contaminants being H₂SO₄-0.27%, Pb ion 0.01%, Cl⁻ ion 0.01% KClO₃-0.37%, and K₂SO₄-0.01%. A simple recrystallization would easily remove these impurities, if warranted, to meet specifications.

D. ANALYTICAL PROCEDURES

1. Lead Dioxide and Lead Sulfate

a. Lead Dioxide - by potassium iodide

The PbO_2 was quantitatively tested by treating it with NaBr, HCl and KI to liberate free iodine which was titrated with standard thiosulfate. Presence of other substances that oxidize, e.g. ClO_3 ion, will affect the results since they too liberate iodine.

Equations:

PbO₂ + 4HC1 + 2NaBr
$$\rightarrow$$
 2PbCl₂ + 2NaCl + Br₂ + 2H₂O
Br₂ + 2Kl \rightarrow 2KBr + l₂
I₂ + Na₂S₂O₃ \rightarrow 2NaI + Na₂S₄O₆

b. Lead dioxide - by hydrogen peroxide

An alternative method is to treat the sample with dilute HCl and a known excess of $\rm H_2O_2$. After reacting, the excess $\rm H_2O_2$ is titrated with standard KMnO₄ solution. Again all other oxidants must be absent.

$$PbO_2 + H_2O_2 + 2HC1 \rightarrow PbCl_2 + 2H_2O_2 + O_2$$

 $H_2O_2 + KMnO_4 + 6HNO_3 \rightarrow 2Mn(NO_3)_2 + 2KNO_3 + 8H_2SO_4$

c. Lead Sulfate

In a mixture of PbO₂ and PbSO₄ the PbSO₄ can be analyzed by converting the mixture entirely to PbSO₄ with concentrated H₂SO₄. Then using either of the methods cited for analysis of PbO₂, the difference between the total PbSO₄ and the PbSO₄ equivalent to the PbO₂ analyzed, will give the amount of PbSO₄ contained in the original mixture.

Equation:

$$PbO_2 + H_2SO_4 - H_2O + PbSO_4 + 1/2O_2$$

2. Chlorate and Perchlorate

a. Chlorate

The method of analysis for chlorate is identical to the PbO₂ method (1-a) where now the ClO_3 ion liberates iodine.

b. Perchlorates by Titanium Trichloride

The method described by Von Eugen Spitalsky and S. Jofa (6) has been modified slightly for use in this work. This method was tested in our laboratory and found to give quite consistent results within the limits of accuracy of ± 1%.

Other oxidizing agents such as chlorate, chlorite, hypochlorite and nitrate which are also reduced by TiCl₃ must be removed completely from the sample being analyzed. The removal of chlorate, chlorite and hypochlorite may be accomplished easily by reduction with sulfur dioxide according to the equation:

$$3H_2O + ClO_3^- + 3SO_2 \rightarrow Cl^- + 3SO_4^- + 6H^+$$

The presence of nitrate ions or nitric acid necessitates the use of a different analytical method, which will be mentioned later.

Since titanous solutions are readily oxidized by air, care must be taken to protect them from contact with air by using an inert atmosphere such as carbon dioxide.

Procedure: After all oxidants other than ClO₄ have been removed, the sample solution (in a 500 ml Erlermeyer flask) is acidified with 50 ml of 10% H₂SO₄, and air excluded from contact with the solution by the addition of dry ice. A measured amount of TiCl₃ solution (previously standardized against potassium dichromate or potassium permanganate) is added. The flask is stoppered with a two hole rubber stopper, containing a tube for the delivery of CO₂ into the flask. The flask is placed on a low temperature hot plate for 1–1.5 hours, to permit complete reduction of perchlorate ion according to the equation:

$$C10\frac{-}{4} + 811^{18} + 811^{4} + C1^{-} + 811^{14} + 411_{20}$$

After heating for the required period of time, the flask is removed from the hot plate and cooled in an ice bath. The stopper is removed and rinsed with water, which has previously been bolled to remove dissolved air and cooled with CO₂ bubbling through it. A piece of dry ice is added to the flask, and the excess TiCl₃ in the sample solution is titrated with standard KMnO₄ solution:

$$571^3 + MnO_4^- + 8H^+ \rightarrow 571^4 + Mn^2 + 4H_{20}$$

The end point may be taken as the first permanent pink coloration imparted to the solution by a drop of KMnO₄; or an oxidation reduction indicator such as diphenylbenzidine may be utilized, 3 drops of a 1% solution in conc. H₂SO₄ being sufficient.

c. Perchlorate by Thermal Decomposition

For samples containing a mixture of nitrate, chlorate and perchlorate, an aliquot of the sample is treated first with SO₂ which reduces chlorate to chloride. The chloride is then determined gravimetrically and calculated to chlorate. The perchlorate is determined by thermal decomposition of another aliquot and subsequent gravimetric determination of the total chloride. The perchlorate is then calculated from the difference in the two chloride results.

V. CONCLUSION

Economical investigation of the various conditions to produce ${\rm KClO_4}$ and the methods to regenerate the ${\rm PbSO_4}$ residue show that the following processes are most favorable.

- a. Potassium perchlorate is formed from potassium chlorate by PbO₂ in an acid medium utilizing the following conditions:
 - 1. Reagent mole ratio H_2SO_4 : PbO_2 : $KClO_3$: $H_2O = 4$: 1:1:17.8.
 - 2. Reaction time 2 hours
 - 3. Temperature 107-125°C
 - 4. Yield of $KClO_A = 85\%$
- b. The spent residue PbSO₄ is regenerated to PbO₂ by chlorination of PbCO₃ produced by direct action of Na₂CO₃ and PbSO₄. The conditions for the carbonation reaction are:
 - 1. Reagent mole ratio $\sim PbSO_4: Na_2CO_3: H_2O = 1: 1.1: 20$
 - 2. Temperature 80-90°C (not critical)
 - 3. Time (minutes) -1.
 - 4. Mixing high speed
 - 5. Chemical Yield Re: PbSO₄ 95%

c. The PbCO3 is then converted to PbO2 by chlorination.

1. Reagent mole ratio - PbCO₃: Na₂CO₃: Cl₂: H₂C= I: 1.2: 1.2: 20

2. Temperature 80°C

3. Chemical yield Re: PbCU₃ - 98%

4. Chemical yield Re: Cl₂ - 99%

The three reactions (a) oxidation, (b) carbonation and (c) chlorination are combined to produce a continuous process. Consult section on "Cyclic Operation" for the detailed description of the process.

Similar high yields are obtained using sodium chlorate to produce sodium perchlorate. In this case crystallization techniques must be modified to suit the high solubility of $NaClO_3$ and $NaClO_4$.

VI. FUTURE WORK

If a detailed cost estimate becomes desirable for producing KClO₄ the following studies should be made:

- 1. Phase diagrams of the system $KClO_4 KClO_3 KHSO_4 H_2SO_4 H_2O$
- 2. Filtration rates for all separations.
- 3. Pilot plant operation

Similar studies should be made also for the analogous sodium perchlorate process.
